NumPy

<u>VandePlas Chapter 2 (external/PythonDataScienceHandbook/notebooks/02.00-Introduction-to-NumPy.ipynb)</u>, <u>Geron notebook (external/handson-ml/tools numpy.ipynb)</u>

Python lists

Lists are heterogeneous: can contain elements of mixed type

Heterogeneity == *slow*

Python interpreter has to constantly examine types

NumPy ndarray

```
In [3]: import numpy as np
```

NumPy n-dimensional arrays (ndarray) are homogenous

- Can be faster because don't waste time examining type of each element
- Can be treated as vectors
- Vector arithmetic via compiled code = fast

Speed comparison

When dealing with large datasets, you need NumPy

Basics of NumPy arrays

<u>VanderPlas (external/PythonDataScienceHandbook/notebooks/02.02-The-Basics-Of-NumPy-Arrays.ipynb)</u>

<u>Vandeplas YouTube: Losing your loops - slides (https://speakerdeck.com/jakevdp/losing-your-loops-fast-numerical-computing-with-numpy-pycon-2015?slide=14)</u>

The most operation on ndarrays is indexing.

ndarray indices are 0-based (i.e, first row/col is numbered 0, not 1)

```
In [10]:
         x = np.arange(0,6)
         Χ
         x[2]
         M = np.arange(0,6).reshape(2,3)
         М
         M[1,1]
         array([0, 1, 2, 3, 4, 5])
Out[10]:
Out[10]: 2
Out[10]: array([[0, 1, 2],
                 [3, 4, 5]]
Out[10]: 4
```

Slicing

• Python (not just NumPy) upper bound of index is NOT inclusive

```
In [11]: print("x: ", x)
    print("x tail: ", x[2:])
    print("x head: ", x[:2])

    x: [0 1 2 3 4 5]
    x tail: [2 3 4 5]
    x head: [0 1]
```

Strides

```
x[start:stop:step]
```

```
In [12]: x[1:5:2]
Out[12]: array([1, 3])
```

Reshaping

```
In [12]: grid = np.arange(1, 10).reshape((3, 3))
    print(grid)

[[1 2 3]
    [4 5 6]
    [7 8 9]]
```

Add dimensions

Concatentation, splitting

You can concatenate multi-dimensional ndarrays:

```
In [15]: M1 = np.array([[1, 2, 3],
                        [4, 5, 6]
         M2 = np.array([ [ 7, 8, 9 ],
                        [ 10, 11, 12]
         M1
         M2
         np.concatenate([ M1, M2 ])
Out[15]: array([[1, 2, 3],
                 [4, 5, 6]]
Out[15]: array([[ 7, 8, 9],
                 [10, 11, 12]])
Out[15]: array([[ 1, 2, 3],
                 [ 4, 5, 6],
[ 7, 8, 9],
                 [10, 11, 12]])
```

You can also specify the dimension on which to concatenate

You can also use vstack (vertical stack) and hstack (horizontal stack)

```
In [17]:
         x = np.array([1, 2, 3])
         grid = np.array([[9, 8, 7],
                           [6, 5, 4]]
         y = np.array([100],
                           [200]
                        ])
         X
         grid
         print("vstack:")
         # vertically stack the arrays
         np.vstack([x, grid])
         print("hstack:")
         У
         grid
         np.hstack( [y, grid])
Out[17]: array([1, 2, 3])
          array([[9, 8, 7],
Out[17]:
                 [6, 5, 4]]
         vstack:
Out[17]: array([[1, 2, 3],
                 [9, 8, 7],
                 [6, 5, 4]])
         hstack:
```

Out[17]: array([[100],

[200]])

Ufuncs

<u>Vandeplass (external/PythonDataScienceHandbook/notebooks/02.03-Computation-on-arrays-ufuncs.ipynb#Introducing-UFuncs)</u>

Math

- element-wise operations
- vectorized for speed
- operator overloading
 - **+**, -, *, /
 - **■** <, ==, >
 - provides natural syntax

```
In [18]: x = np.array( np.arange(0,10))
    print("x: ", x)
    print("+1: ", x + 1)
    print("+1 verbose: ", np.add(x,1))
    print("-1: ", x -1)

x: [0 1 2 3 4 5 6 7 8 9]
    +1: [1 2 3 4 5 6 7 8 9 10]
    +1 verbose: [1 2 3 4 5 6 7 8]
+1 verbose: [1 2 3 4 5 6 7 8]
```

Aggregates

<u>Vanderplass (external/PythonDataScienceHandbook/notebooks/02.03-Computation-on-arrays-ufuncs.ipynb#Aggregates)</u>

- Aggregation: taking a one-dimensional slice of an ndarray and reducing it to a scalar
 - also known as reduce

Best illustrated with an example

```
In [19]: x = np.arange(1, 6)
    print("x: ", x)
    print("x reduced by add: ",np.add.reduce(x))

# Less verbose synonym
    print("x reduced by add, via sum", x.sum())

x: [1 2 3 4 5]
    x reduced by add: 15
    x reduced by add, via sum 15
```

Aggregates on multi-dimensional ndarray: choose your dimension

```
In [20]: x = np.arange(1,7).reshape(2,3)
    print("x: ", x)

    print("x reduced on first dimension: ", x.sum(axis=0))

    print("x reduced on second dimension: ", x.sum(axis=1))

x: [[1 2 3]
    [4 5 6]]
    x reduced on first dimension: [5 7 9]
    x reduced on second dimension: [6 15]
```

Cumulative

Closely related to reduce: accumulate

- running operations, e.g, running sum

```
In [21]: print("x: ", x)
    print("x running sum: ", np.add.accumulate(x)) # NOTE: not a method ON x; x is
    a parameter

# Less verbose synonym. n.b., WITHOUT an axis arg,, it will flatten x before sum
    ming
    print("x running sum via cumsum: ", x.cumsum(axis=0))

x: [[1 2 3]
    [4 5 6]]
    x running sum: [[1 2 3]
    [5 7 9]]
    x running sum via cumsum: [[1 2 3]
    [5 7 9]]
```

Broadcasting

<u>Vanderplass (external/PythonDataScienceHandbook/notebooks/02.05-Computation-on-arrays-broadcasting.ipynb)</u>

You hopefully intuitively understand what NumPy does when a binary operator is applied to 2 identically-shaped arguments

```
In [22]: a = np.array([0, 1, 2])
b = np.array([5, 5, 5])
a + b
Out[22]: array([5, 6, 7])
```

But what happens if the two arguments have different shape? Simplest case: one argument is dimension 0 or 1:

```
In [23]: print("a: ", a)
  print("a + 1: ", a+1)

a: [0 1 2]
  a + 1: [1 2 3]
```

Next case: what if one argument is identical to the other EXCEPT is missing a dimension:

NumPy took a one dimensional ndarray a and treated it like a 2-d ndarray by repeated it's rows

This is called **broadcasting**

Broadcasting follows some simple rules (quoted from <u>Vanderplass</u> (<u>external/PythonDataScienceHandbook/notebooks/02.05-Computation-on-arrays-broadcasting.ipynb</u>)):
